key words

impulse cutting theory, boring lathe, face mill machine, turning, milling, grinding

We have described technological methods for solving the problem of increasing the productivity and the machining surfaces of bends and split tees quality. This is necessary to prepare them for subsequent welding.

We have scientifically substantiated and tested a new technology for processing the bends end with an external pipe diameter of 720–1400 mm. A new technology is offered instead of turning end faces of bends and split tees on face-bore type-boring machines with numerical-program control. In this operation, the removal of the total allowance of 15 mm occurs in five passes.

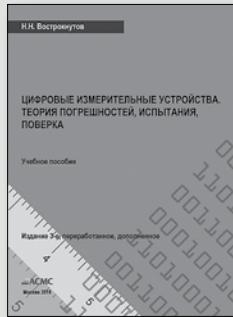

The proposed technology allows milling of the entire allowance in a single pass, on the same machine that has undergone a small modernization. 11 kW electrical milling spindle was installed on the caliper for the boring cutters. When using end mills with a diameter of 20–25 mm, with the number of teeth equal to 4, 5, 6, 9, the average removal time for the allowance was 3 minutes, whereas for boring it is 4.5 minutes. On average, we managed to reduce the machine time for trimming by one and a half times. The durability of the cutters is high.

We also explored other ways to remove large allowances, instead of ineffective boring.

Цифровые измерительные устройства. Теория погрешностей, испытания, поверка

Учебное пособие / Издание 3-е, пер. и доп. — М.: АСМС, 2018

Представлена полностью переработанная книга автора «Испытания и поверка цифровых измерительных устройств» (1990 г.), в связи с важными изменениями в элементной базе и схемотехнике, применяемой при разработке ЦИУ, а также иными принципами построения ЦИУ. Излагаются основы теории погрешностей ЦИУ, методы расчета составляющих погрешностей измерений, а также методы испытаний и способы определения и контроля погрешностей ЦИУ. Книга полезна для инженеров и научных работников, занимающихся испытаниями и разработкой ЦИУ, а также работников метрологических служб.
