We have investigated and justified the possibility of using miniature ampoules of reference points as reference measures for reproducing and transmitting the temperature unit during verification (certification) of liquid thermostats. The advantage of these ampoules is a small volume, high metrological reliability, as well as an acceptable cost due to the small weight (less than 10 g) of especially pure metals used in them. We have experimentally tested and propose a method for determining the actual temperature of the coolant in a liquid thermostat using a reference point of solidification of sodium in a miniature ampoule and a multi-solder differential thermocouple. The advantage of the considered method in comparison with the traditional one based on the use of reference platinum thermometers is the simplicity and reliability of the devices implementing it. The technique can be used for certification (verification) of liquid thermostats using miniature ampoules with reference points of other metals, such as gallium, indium, tin and zinc.
